

Shared Learning Architecture & Strategy

Several learning efforts were already underway. The harder question was how to make them work as one system.

What should be shared across the group, and what should each specialty make its own?

A groupwide learning program, new-hire development, entry resources, and specialist development paths were all in motion. The group needed common expectations, behavior standards, and a measurement approach while each capability developed its own practice.

I led the learning architecture: defining the common core and behavior-first approach, then connecting pathways, practice, resources, and measurement into one operating model. I collaborated with leadership to develop and execute this strategy.

I defined the skills and behaviors people needed to build, then identified how each team would apply them. Observable behaviors guided the architecture, with practice and support connected to work.

One core. Specialized practice.

01 / Shared core

Skills, behaviors, and expectations

02 / Each team's pathways

Example: design preflight

03 / Connected support

Practice, resources, contribution, reuse

04 / Measurement

Current signals; outcomes still to assess

Team leaders validate and own measures.

Illustrative reconstruction; not an internal artifact.

Simplified portfolio reconstruction of the operating model; not an original internal artifact.

Start with what people do. Then build the system around it.

Shared: identity, expectations, behavior standards, and a measurement approach. Specialized: each team's practice, pathways, and leader-owned success measures. Learning journeys, the resource hub, and contribution and reuse connect the operating system.

The practice is the point.

AI-native workflows ask people to create a workspace for each new project and ship more code, designs, or experiences. We provided a prompt library, discovery-meeting coaching, and an AI tool selection guide alongside preflight checks.

- Run the check: The designer runs a preflight on the design.
- Review against standards: The workflow grades the design against standards, concepts, frameworks, and similar criteria.
- Choose remediation: The designer receives a report and decides how to remediate.
- Share review evidence: Managers and leaders were asked to request the scorecard when designers deliver work.

This example shows where support lives in the system. We are not claiming that the prompt improved call quality without an evaluation of that outcome.

Measure the system. Then ask what changed.

Team leaders help validate the framework and own success measures. The current signals tell us about use and contribution. The longer-term test is whether this work improves performance and business outcomes.

Adoption / Current signal

AI tool usage.

Contribution / Current signals

Pull requests, code changes proposed for review, and resource-hub artifacts.

Design review / Individual scorecards

Preflight results go to designers; no improvement trend is reported here.

Business outcomes / Intended

Results not yet supplied.

These counts alone do not establish behavior quality or a business result.

Specific values and outcome results are not included here. This case shows the operating architecture and the measurement approach, with those evidence limits made explicit.

INTERPRETATION & CONFIDENTIALITY

The operating architecture is described from the project owner's account. No original prompt, call, or design artifact is reproduced. Confidentiality-safe adaptation of ongoing professional work. Group and initiative names have been changed.
